

5.4.5 NATURAL GAS DEVELOPMENT

This section provides a profile and vulnerability assessment for the hazard posed by incidents involving the natural gas infrastructure within Chenango County.

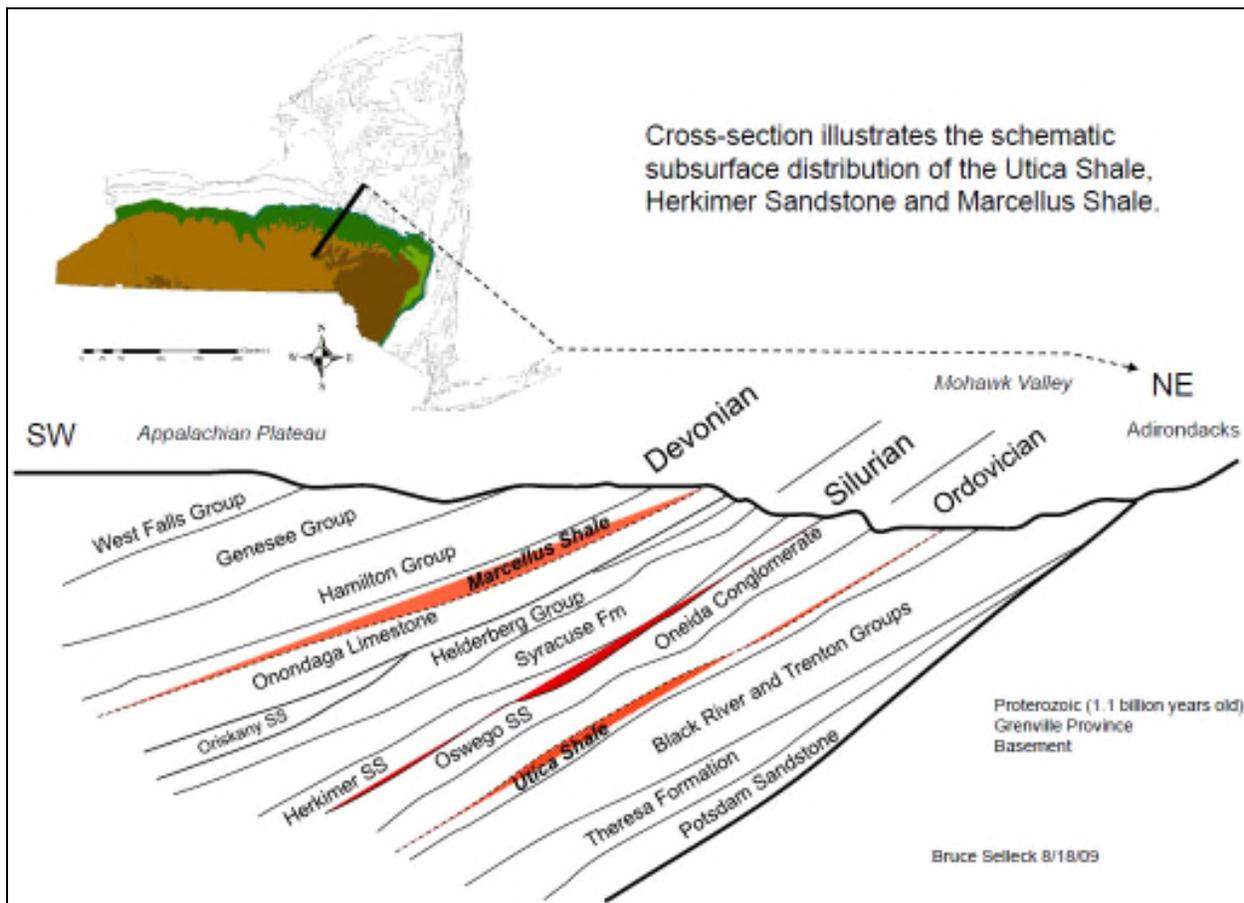

5.4.5.1 Hazard Profile

This section provides a profile and vulnerability assessment for the hazards posed primarily by the ongoing and potential development of the natural gas industry and natural gas infrastructure within Chenango County.

Description

Natural gas is a mixture of hydrocarbon gases- mostly methane with some ethane, propane, and butane (Selleck, 2009). It is created by the breakdown of organic matter at high temperature and pressure under the Earth’s surface. Different layers of sedimentary rock in the Earth’s crust have varying potential to contain natural gas. Figure 5.4.5-1 shows an exaggerated cross-section of the sedimentary rock layers in New York State around Chenango County (Selleck, 2009).

Figure 5.4.5-1. Sedimentary Rock Layers

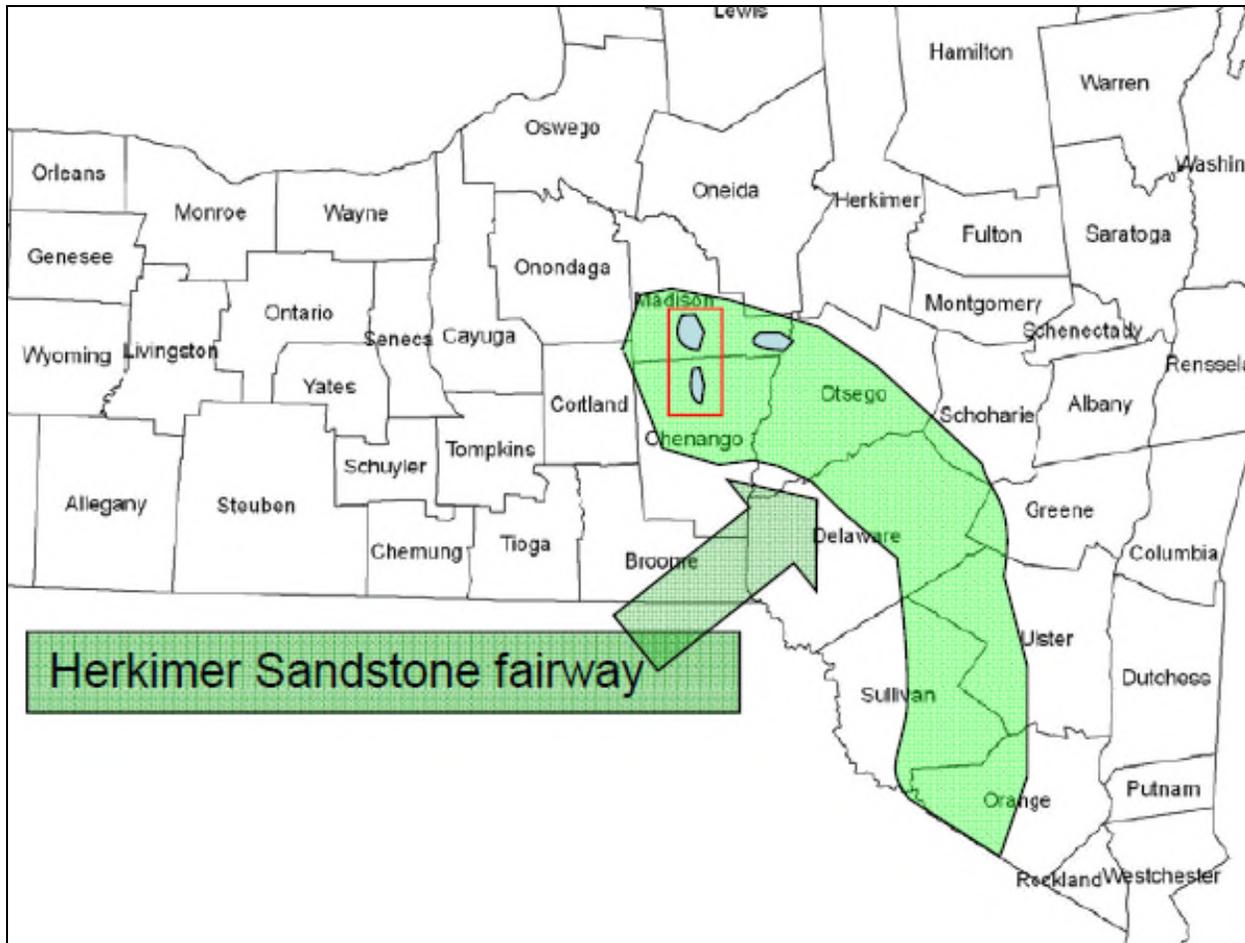

Source: Selleck, 2009

Three layers of rock are particularly relevant to natural gas drilling in Chenango County. The first is the Herkimer Sandstone, which is the layer from which most of the active natural gas wells in Chenango County draw natural gas, as shown in Figure 5.4.5-2. The indicated “fairway” is the region with a high probability of

drawing natural gas from the Herkimer Sandstone. The red box highlights an area of Madison and Chenango Counties in which there are numerous active natural gas wells drawing from the Herkimer Sandstone.

Figure 5.4.5-2. Herkimer Sandstone Fairway

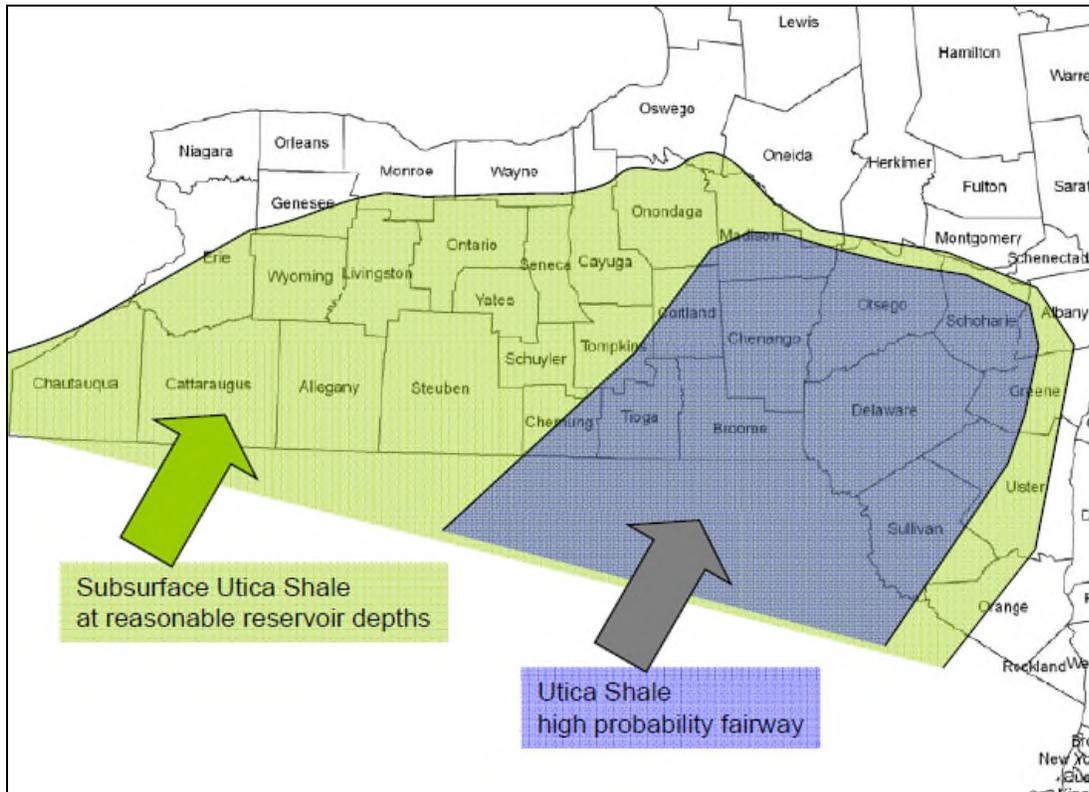

Source: Selleck, 2009

The other two layers, the Marcellus Shale and Utica Shale, have recently been targeted by natural gas drilling companies in West Virginia, Pennsylvania, Ohio, and New York State. However, unlike the Herkimer Sandstone, these two layers require horizontal drilling and high volume hydraulic fracturing of the rock itself to release sufficient quantities of natural gas to make drilling economical. Figures 5.4.5-3 and 5.4.5-4 show the Utica Shale and Marcellus Shale fairways, respectively. All of Chenango County is within the Utica Shale fairway, making the entire County potentially attractive for natural gas drilling in the Utica Shale. All but the northern parts of Chenango County are within the Marcellus Shale fairway.

Once the gas has been extracted from the ground, it must be distributed to customers. In New York State, 4.7 million natural gas customers are served by a local gas distribution company (New York State Energy Planning Board, 2009). New York State Electric and Gas (NYSE&G), has natural gas franchise agreements with several municipalities in Chenango County (as shown in Figure 5.4.5-5) where the infrastructure is available. At this time the primary natural gas customers in Chenango County are residents/businesses in close proximity to the NYSE&G pipeline or the City of Norwich and Village of Oxford. The franchise agreements allows for infrastructure development to provide additional service to potential natural gas customers in Chenango County.

Figure 5.4.5-5. New York State Gas Service Territories

Source: New York State Energy Planning Board, 2009

Note: The location of Chenango County is indicated by the red circle.

Natural gas is primarily transported by pipelines. Interstate pipelines are regulated by the Federal Energy Regulatory Commission (FERC) and intrastate pipelines are regulated by the New York State Public Service Commission (NYSPSC). The intrastate pipelines are under the jurisdiction of the NYSPSC Gas Safety Division (Chenango County Natural Gas Advisory Committee, 2011). Low-pressure (<125 psi) gathering pipelines are regulated by the Gas Safety Division. Towns do not have regulatory authority over them. The PSC has regulatory authority over intrastate lines at all levels, including, but not limited to, the safety division (Planning Committee Input, 2014).

There are a few potential negative impacts of natural gas drilling, which could adversely affect Chenango County. First, natural gas could leak from the well site. This could cause a hazardous situation if the gas were to collect and pool in or near occupied structures, as it could cause direct health effects or ignite. Ignition and explosion of natural gas is the second negative potential impact of natural gas drilling. Third, natural gas and/or flowback fluids could contaminate the environment. Finally, the increased truck traffic directly related to well drilling could result in an increase of transportation accidents. These impacts are described in the sections below.

Extent

Natural gas is flammable and has the potential to cause significant impacts (Lycoming County, 2010). If a large volume of natural gas escapes from a well or pipeline, it has the potential to explode. This explosion, depending on its magnitude, could injure or kill people (potentially overwhelming the local emergency medical services [EMS]), destroy property, cause urban or wildland fires, close roads, force evacuations, cause power or telephone outages (if transmission lines are damaged), etc.

The extent of impacts from natural gas incidents depends on several factors (Lycoming County, 2010):

- Compliance with applicable site design, building, and fire codes
- Maintenance of equipment
- Weather conditions
- Micro-meteorological effects of buildings and terrain
- Warning time for affected populations
- Response time for emergency response units

Site design, and building and fire code compliance are the primary factors which can be controlled by humans. By ensuring that the drill site is properly designed, drilling operations follow established regulations, well(s) are properly designed and constructed. It is also important to ensure that drilling equipment is inspected and maintained regularly, in accordance with equipment specifications and regulations, so that any defects can be addressed before a release.

Should there be an incident that releases natural gas from the well site or pipeline, weather conditions and micro-meteorological effects will affect the spread of any natural gas released in the incident. Natural gas is lighter than air, and will rise when released. Ambient weather conditions and effects of terrain or buildings may keep the gas closer to the ground.

If natural gas escapes due to an incident, and it has the potential to affect people and property, those effects will depend on the warning time available for potentially-affected populations to seek appropriate shelter or evacuate the area. The sooner a qualified emergency response unit, whether from the local community or the infrastructure operator, arrives to address any incidents and releases, the less potential for negative consequences exists.

According to the 2012 *Emergency Response Guidebook* published by the U.S. Department of Transportation (US DOT), a large spill of flammable gas, including natural gas from a well site or a point along a pipeline, may result in an initial downwind evacuation of ½ mile (USDOT, 2012).

Location

The locations of well sites are tracked by the New York State Department of Environmental Conservation (NYSDEC). Locations of wells in Chenango County are shown in Figure 5.4.5-6. There are currently 57 natural gas wells in Chenango County. Most gas wells are located in the Town of Smyrna in the northern part of the County.

Figure 5.4.5-6. Natural Gas Wells Completed and Proposed in Chenango County

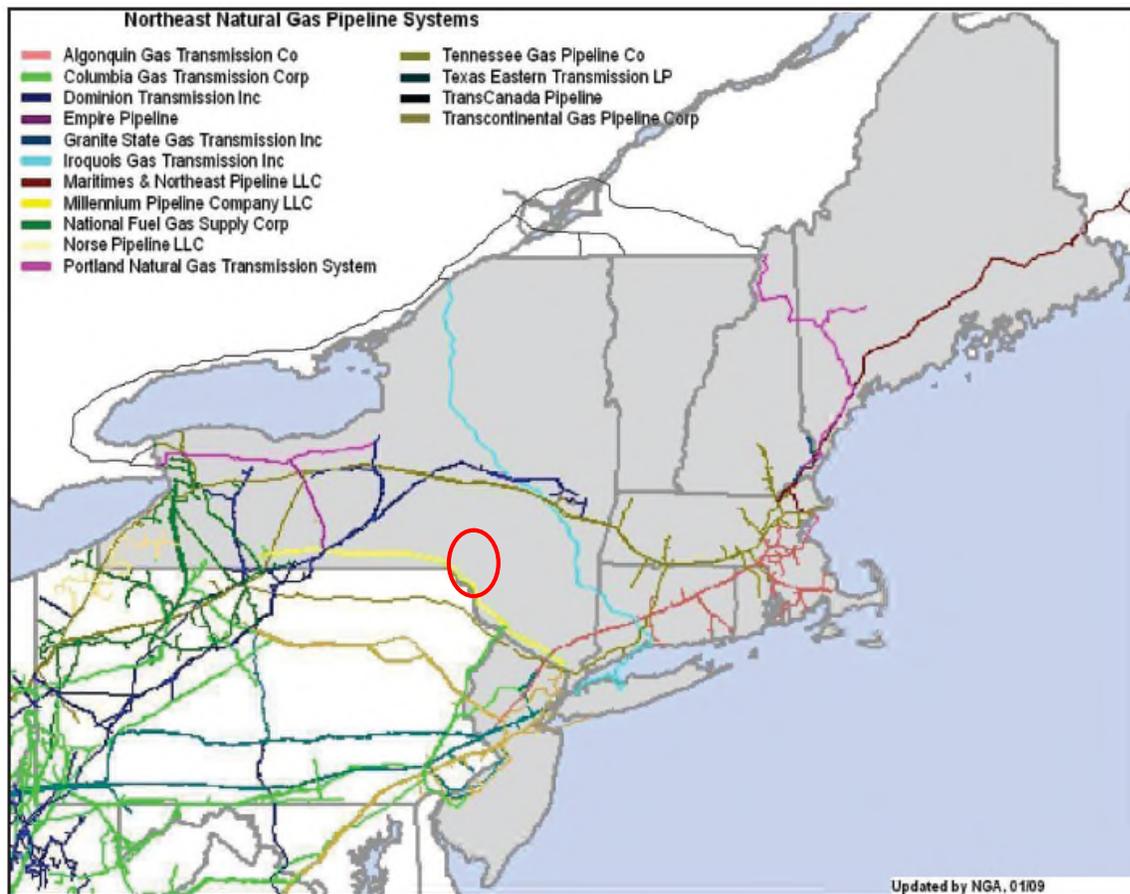

Source: NYSDEC Environmental Navigator, 2013
Note: Chenango County is outlined in green.

There are no major (from a national perspective) pipelines running through Chenango County, as shown in Figure 5.4.5-7. The closest major pipeline is the Millennium Pipeline, running east-west, just south of Chenango County and the Tennessee and Dominion pipelines to the north. The Teppco Pipeline is a pipeline running east-west across Chenango County, through the Towns of McDonough, Preston, Oxford, and Norwich (Planning Committee, 2007), supplying multiple products (Planning Committee Input, 2014) but not natural gas.

There is a low-pressure (< 125psi) natural gas gathering pipeline system connecting gas wells in the towns of Smyrna, Plymouth, and Preston. The specific locations of these pipelines have been deemed confidential due to issues related to homeland security. They are on file at the County Bureau of Fire.

Figure 5.4.5-7. Major Pipelines in the Northeast United States

Source: New York State Energy Planning Board, 2009
Note: The location of Chenango County is indicated by the red circle.

A new major pipeline, the proposed 124 mile, 30-inch diameter Constitution Pipeline, is in the initial stages of development. In September 2013, the Environmental Review was submitted to the Federal Energy Regulatory Commission (FERC), which has subsequently been federally approved. Currently the only permits that are outstanding are NYSDEC permits for several water crossings. The Constitution Pipeline will likely run through the Towns of Afton and Bainbridge in the southern part of the County, as shown in Figure 5.4.5-8.

Table 5.4.5-1 summarizes natural gas wells identified in the NYSDEC Oil and Gas database (<http://www.dec.ny.gov/cfm/xtapps/GasOil/>) as of December 2015. This table further identifies existing

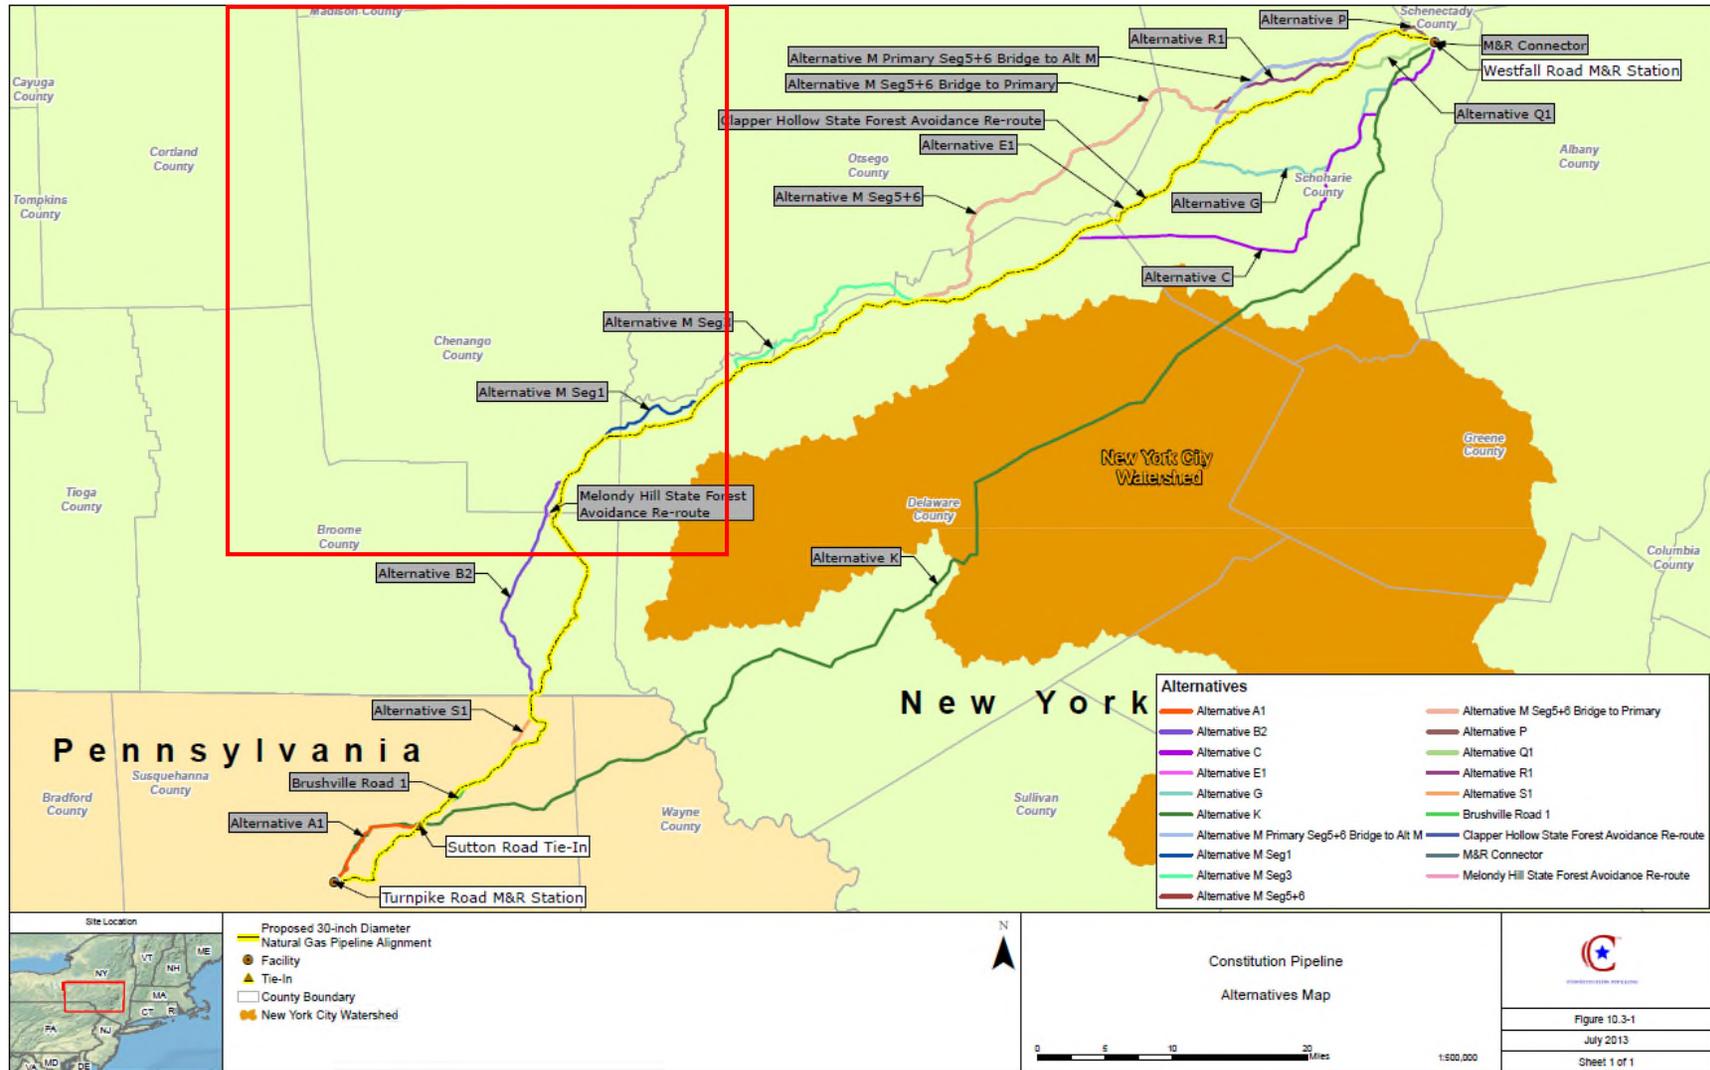

Section 5.4.5: Risk Assessment – Natural Gas Development

and proposed natural gas pipelines as identified by the Chenango County Department of Planning and Development, and Commerce Chenango as of December 2015.

Previous Occurrences and Losses

Many sources provided information regarding previous occurrences of incidents at natural gas well sites and transmission pipelines, and possible environmental contamination due to the chemicals used in the drilling process, throughout the shale regions of Pennsylvania and New York. However, there were few records of incidents in Chenango County.

In July 2008, a faulty valve on a well head blew out during pressure testing, causing eye and ear injuries to a worker (DeCordova, 2008). The work crew took 30-45 minutes to get the resulting gas leak under control. No property damages were recorded.

On January 5, 2009, a fire erupted at a drilling rig in the Town of Smyrna (DeCordova, 2009). Rocks were thrown out of the wellhead. One struck and broke a fluorescent light, causing a spark that ignited the gas coming from the well. The drilling rig was severely damaged, but no injuries were reported.

Probability of Future Events

As natural gas drilling has expanded in New York State, state and local representatives have used Pennsylvania’s experience with the natural gas industry to inform their regulations and practices, to try to avoid the problems that Pennsylvania has experienced (NYSDEC, 2011). Table 5.4.5-2 shows a sample of these problems, and potential solutions identified in New York’s 2011 revised draft Supplemental Generic Environmental Impact Statement (rdSGEIS). These solutions were proposed to minimize the probability of New York State’s communities, including Chenango County, experiencing these problems associated with natural gas drilling.

Table 5.4.5-2. Problems and Solutions Related to Natural Gas Drilling

Issue	Problems Identified	SGEIS Solution
<ul style="list-style-type: none"> Methane Gas Migration 	<ul style="list-style-type: none"> Improperly cased and cemented wells Excessive pressures 	<ul style="list-style-type: none"> Proper well casing design and inspection Specific requirements for cementing practices, testing, and use of intermediate casing
<ul style="list-style-type: none"> Fracturing Fluid Releases 	<ul style="list-style-type: none"> Poor site design Equipment failure Stormwater controls failure 	<ul style="list-style-type: none"> Inspection of well site Pressure testing of equipment Stormwater permitting Secondary containment Closed loop systems
<ul style="list-style-type: none"> Uncontrolled Wellborne Release of Flowback Water and Brine 	<ul style="list-style-type: none"> Inadequate equipment Lack of certified well control personnel 	<ul style="list-style-type: none"> Pressure testing of equipment Use of specialized equipment Presence of a certified well control specialist
<ul style="list-style-type: none"> High Total Dissolved Solids (TDS) Discharges 	<ul style="list-style-type: none"> Lack of regulations for surface water quality 	<ul style="list-style-type: none"> Permitting and approval process for proposed discharge flowback water or brine to wastewater treatment plants In-stream limits for TDS State Pollutant Discharge Elimination System (SPDES) permit, which limits TDS based on stream’s capacity to assimilate TDS

Future events related to natural gas exploration could also occur. Lycoming County, Pennsylvania, studied the increase in truck traffic through the county related to natural gas drilling (Lycoming County, 2010). Table 5.4.5-3 shows the increase in truck traffic from each well.

Table 5.4.5-3. Truck Loads for One Gas Well

Total Truck Loads for One Gas Well

Type of Vehicle	No. of Axes	Loaded Weight	Empty Weight	One Way Trips	Comments
Drilling Operations					
Rock Hauler	5	84,000	35,000	70	Pad Construction
Rig (install)	5	100,000	n/a	2	Rig Set-up

Production					
Tank Truck	5	80,000	35,000	353	Empty Dehydration Tanks

1,134 Heavy Truck Loads Plus 353 Trucks / Yr (Maint.) / Well Head

In Section 5.3, the identified hazards of concern for Chenango County were ranked. The probability of occurrence, or likelihood of the event, is one parameter used for ranking hazards. Based on historical records and input from the Planning Committee, the probability of occurrence for natural gas incidents at well sites in the County is considered ‘Frequent’ (likely to occur more than once every 25 years, as presented in Table 5.3-3). Based on Cornell University’s analysis of chemical spills related to drilling operations in Pennsylvania, Chenango County can expect one truck accident related to the natural gas industry every four years (Chenango County Natural Gas Advisory Committee, 2011).

Climate Change Impacts

It is difficult to assess the impacts that climate change will have on the frequency and severity of natural gas incidents in Chenango County. Unlike drought, winter storms, or flooding, which are natural hazards directly dependent on the climate, natural gas drilling and therefore incidents involving the release of natural gas are man-made issues. As such, any link between climate change and the risks associated with the natural gas industry in the County cannot be made at this time.

5.4.5.2 Vulnerability Assessment

To understand risk, a community must evaluate what assets are exposed or vulnerable in the identified hazard area. For natural gas incidents, the entirety of Chenango County has been identified as the hazard area. Therefore, all assets in Chenango County, as described in the County Profile section, are vulnerable to these incidents. The following text evaluates and estimates the potential impact of natural gas incidents on the County including:

- Overview of vulnerability
- Data and methodology used for the evaluation
- Impact on: (1) life, health and safety of residents, (2) general building stock, (3) critical facilities, (4) economy, and (5) future growth and development
- Effect of climate change on vulnerability
- Change of vulnerability as compared to that presented in the 2008 Chenango County Hazard Mitigation Plan
- Further data collections that will assist understanding this hazard over time

Overview of Vulnerability

Chenango County sits over one or more strata of natural gas-bearing rock. Several natural gas drilling companies have already begun to extract natural gas from the bedrock below the County and there is potential for more to come. Drilling for natural gas is relatively new to Chenango County; however, there is a history of the industry prospecting in the County. Data from NYSDEC shows that first natural gas well recorded in the County was drilled in the Town of Norwich in the late 1800's. A dry wildcat well was drilled in the Town of Columbus in 1948. Impacts from natural gas development include the following:

- Land disturbances during the drilling phase of one to two acres per pad site for conventional wells and up to five acres for a multi-well pad where HVHF techniques are used. Once drilling is complete and the pad site reclaimed, the area occupied by the producing wells would shrink from a tenth of an acre to approximately one acre for a six-well site.
- Additional pipeline would need to be constructed if the fields expand beyond the reach of the current gathering line systems.
- The County could expect to see an influx of workers from outside of the area; thus, occupying some, if not most, of hotel and motel rooms and some seasonal rentals including cottages and campsites throughout Chenango County.
- The County may experience road impacts at the state, town, and county level with the possibility of intermittent localized traffic disruptions.
- The County may see additional retail activity, especially at eateries and those businesses that supply goods and services the natural gas industry uses, ranging from gravel to welding supplies.
- Tax revenues that would flow to the County, municipalities, school districts and other entities that rely on the property tax system as a source of funding.
- An additional income that would be distributed to the holders of the mineral rights.

Outside of the risk of natural gas development, perhaps the greatest current risk with respect to natural gas in the county is the risk of a pipeline rupture involving the NYSEG system would leave several thousand residents and many public buildings without heat. Further, the current above-ground storage and transport of natural gas, and the widespread use for domestic energy, also poses considerable risk.

Data and Methodology

Due to a lack of quantifiable loss information, a qualitative assessment was conducted to evaluate the assets exposed to this hazard and the potential impacts associated with this hazard.

Impact on Life, Health and Safety

The entire population of Chenango County is vulnerable to natural gas development incidents. According to the 2010 U.S. Census, the County had a population of 50,477. During a natural gas development incident, those populations located near the site of the incident are the most vulnerable and may need to seek appropriate shelter or evacuate the area. According to the *2012 Emergency Response Guidebook* published by the U.S. Department of Transportation (US DOT), a large spill of flammable gas, including natural gas from a well site or a point along a pipeline, may result in an initial downwind evacuation of ½ mile (USDOT, 2012).

Impact on General Building Stock and Critical Facilities

Any facilities located near natural gas wells are vulnerable to natural gas development incidents. Natural gas development incidents can largely impact water quality and water supply; therefore, general building stock and critical facilities related to water supply may be more vulnerable. As previously stated, the hazard area around a natural gas drilling site encompasses an area with a radius of one-half mile, which is the initial downwind evacuation distance for large spills. With this being stated, building or critical facility in Chenango County located within one-half mile of a natural gas drilling site is vulnerable.

Impact on Economy

The impact natural gas incidents have on the economy and estimated dollar losses are difficult to measure and quantify.

Impact of Future Growth and Development

As discussed in Section 4, areas targeted for future growth and development have been identified across the County. Any areas of growth could be potentially impacted by natural gas incidents because the entire planning area is exposed and vulnerable.

Change of Vulnerability

The natural gas incident hazard is a new hazard of concern for the County and was not discussed previously in the 2008 HMP. With the increase in natural gas well installations throughout the County, the Planning Committee identified this as a hazard of concern for the 2015 HMP Update.

Additional Data and Next Steps

For the Plan Update, any additional information regarding localized concerns and past impacts will be collected and analyzed. This data will be developed to support future revisions to the plan. Mitigation efforts could include building on existing New York State, Chenango County, and local efforts.
